# 2019 AMC 8 Solutions

#### **Problem 1**

Ike and Mike go into a sandwich shop with a total of \$30.00 to spend.

Sandwiches cost \$4.50 each and soft drinks cost \$1.00 each. Ike and Mike plan to buy as many sandwiches as they can and use the remaining money to buy soft drinks. Counting both soft drinks and sandwiches, how many items will they buy?

(A) 6 (B) 7 (C) 8 (D) 9 (E) 10

#### **Solution 1**

We maximize the number of sandwiches Mike and Ike can buy by finding the lowest multiple of \$4.50 that is less than \$30. This number is 6.

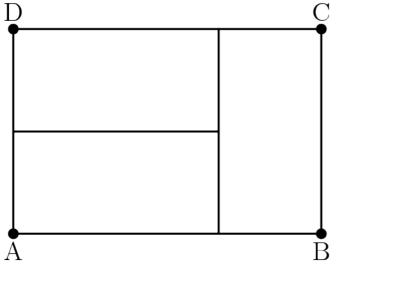

Therefore, they can buy 6 sandwiches for  $\$4.50 \cdot 6 = \$27$ . They spend the remaining money on soft drinks, so they buy 30-27=3 soft drinks.

Combining the items, Mike and Ike buy  $6+3=9\,\mathrm{soft}$  drinks.

The answer is

# **Problem 2**

Three identical rectangles are put together to form rectangle ABCD, as shown in the figure below. Given that the length of the shorter side of each of the smaller rectangles is 5 feet, what is the area in square feet of rectangle ABCD?

**(A)** 45

**(B)** 75

**(C)** 100

**(D)** 125 **(E)** 150

#### **Solution 1**

We know that the length of the shorter side of the 3 identical rectangles are all 5 so we can use that by seeing that the longer side of the right rectangle is the same as 2 of the shorter sides of the other 2 left rectangles. This means that  $2 \cdot 5 = 10$  which is the longer side of the right rectangle, and because all the rectangles are congruent, we see that each of the rectangles have a longer side of 10 and a shorter side of 5. Now the bigger rectangle has a shorter length of 10(because the shorter side of the bigger rectangle is the bigger side of the shorter rectangle, which is 10) and so the bigger side of the bigger rectangle is the bigger side of the smaller rectangle + the smaller side of the smaller

rectangle, which is 10+5=15 . Thus, the area is  $15\cdot 10^{\circ}=150$  for

#### Solution 2

Using the diagram we find that the larger side of the small rectangle is 2 times the length of the smaller side. Therefore the longer side is  $5 \cdot 2 = 10$ . So the area of the identical rectangles is  $5 \cdot 10 = 50$ . We have 3 identical rectangles that form the large rectangle. Therefore the area of the large rectangle

is 
$$50 \cdot 3 = \boxed{\textbf{(E)} \ 150}$$
. ~~fath2012

We see that if the short sides are 5, the long side has to be  $5 \cdot 2 = 10$  because the long side is equal to the 2 short sides and because the rectangles are congruent. If that is to be, then the long side of the

BIG rectangle (rectangle ABCD) is 10+5=15 because long side + short side of the small rectangle is 15. The short side of rectangle ABCD is 10 because it is the long side of the short rectangle.

Multiplying 15 and 10 together gets us  $15 \cdot 10$  which is  $(\mathbf{E}) \ 150$  ~mathboy282

#### **Problem 3**

Which of the following is the correct order of the

fractions 
$$\frac{15}{11}, \frac{19}{15},$$
 and  $\frac{17}{13},$  from least to greatest?

$$\textbf{(A)} \ \frac{15}{11} < \frac{17}{13} < \frac{19}{15} \qquad \textbf{(B)} \ \frac{15}{11} < \frac{19}{15} < \frac{17}{13} \qquad \textbf{(C)} \ \frac{17}{13} < \frac{19}{15} < \frac{15}{11} \qquad \textbf{(D)} \ \frac{19}{15} < \frac{15}{11} < \frac{17}{13} \qquad \textbf{(E)} \ \frac{19}{15} < \frac{17}{13} < \frac{15}{11} < \frac{15} < \frac{15}{11} < \frac{15}{11} < \frac{15}{11} < \frac{15}{11} < \frac{15}{11} <$$

#### Solution 1

Consider subtracting 1 from each of the fractions. Our new fractions would then

be 
$$\frac{4}{11},\frac{4}{15},$$
 and  $\frac{4}{13}$ . Since  $\frac{4}{15}<\frac{4}{13}<\frac{4}{11}$ , it follows that the answer

$$\mathbf{(E)} \frac{19}{15} < \frac{17}{13} < \frac{15}{11}$$

-will3145

#### **Solution 2**

We take a common

denominator:

$$\frac{15}{11}, \frac{19}{15}, \frac{17}{13} = \frac{15 \cdot 15 \cdot 13}{11 \cdot 15 \cdot 13}, \frac{19 \cdot 11 \cdot 13}{15 \cdot 11 \cdot 13}, \frac{17 \cdot 11 \cdot 15}{13 \cdot 11 \cdot 15} = \frac{2925}{2145}, \frac{2717}{2145}, \frac{2805}{2145}.$$

Since 2717 < 2805 < 2925 it follows that the answer

$$(\mathbf{E})\frac{19}{15} < \frac{17}{13} < \frac{15}{11}$$

- -xMidnightFirex
- ~ dolphin7 I took your idea and made it an explanation.

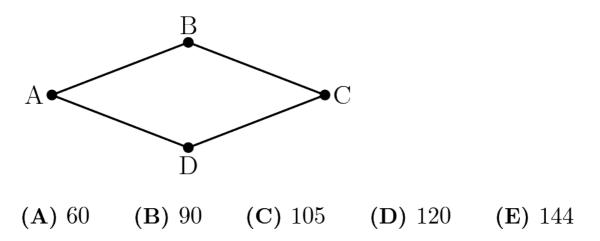

## **Solution 3**

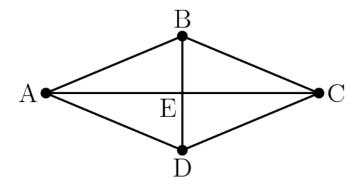

$$\frac{x}{y} > 1 \qquad \frac{x+z}{y+z} < \frac{x}{y} \text{. Hence, the answer}$$
 
$$(\mathbf{E}) \frac{19}{15} < \frac{17}{13} < \frac{15}{11}$$

This is also similar to Problem 20 on the AMC 2012.

## **Problem 4**

Quadrilateral ABCD is a rhombus with perimeter 52 meters. The length of diagonal  $\overline{AC}$  is 24 meters. What is the area in square meters of rhombus ABCD?

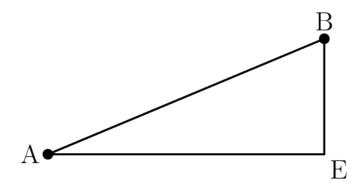

A rhombus has sides of equal length. Because the perimeter of the rhombus

is 
$$52$$
, each side is  $\frac{52}{4}=13$  . In a rhombus, diagonals are perpendicular and bisect each other, which means  $\overline{AE}$  =  $12$  =  $\overline{EC}$ .

Consider one of the right triangles:

 $\overline{AB}$  = 13, and  $\overline{AE}$  = 12. Using Pythagorean theorem, we find that  $\overline{BE}$  = 5.

Thus the values of the two diagonals are  $\overline{AC}$  = 24 and  $\overline{BD}$  = 10. The area

of a rhombus is = 
$$\frac{d_1*d_2}{2}$$
 =  $\frac{24*10}{2}$  =  $120$ 

# Solution 2 (Heron's)

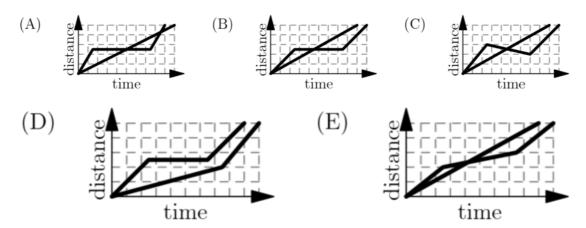

Since a rhombus has sides of

$$AB=BC=CD=DA=\frac{52}{4}=13$$
 equal length, ABC,  $AB=BC=13$  and  $AC=24$ . Using Heron's formula, we have 
$$[ABCD]=[ABC]+[ACD]=2[ABC]=2\sqrt{25*12*12*1}$$
 . Simplifying, we have 
$$[ABCD]=2*60=\boxed{\textbf{(D)}120}$$
 . ~~RWhite

# **Problem 5**

A tortoise challenges a hare to a race. The hare eagerly agrees and quickly runs ahead, leaving the slow-moving tortoise behind. Confident that he will win, the hare stops to take a nap. Meanwhile, the tortoise walks at a slow steady pace for the entire race. The hare awakes and runs to the finish line, only to find the tortoise already there. Which of the following graphs matches the description of the race, showing the distance d traveled by the two animals over time t from start to finish?

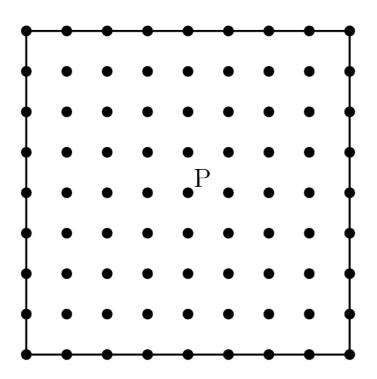

Solution 1 (Using the answer choices)

First, the tortoise walks at a constant rate, ruling out (D) Second, when the hare is resting, the distance will stay the same, ruling out  $(E)_{\mathrm{and}}(C)$ . Third. the tortoise wins the race, meaning that the non-constant one should go off the graph last, ruling out (A). Therefore, the answer (B) is the only one left.

#### **Problem 6**

There are  $81\,\mathrm{grid}$  points (uniformly spaced) in the square shown in the diagram below, including the points on the edges. Point P is in the center of the square. Given that point  ${\cal Q}$  is randomly chosen among the other 80 points, what is the probability that the line PQ is a line of symmetry for the square?

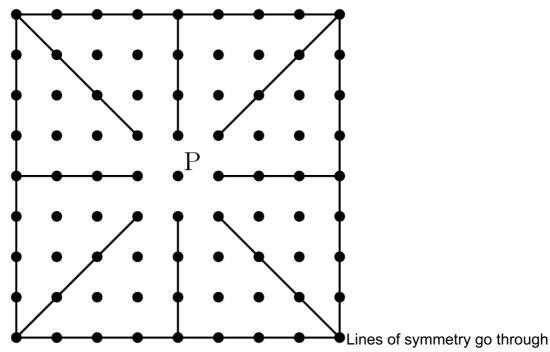

(A) 
$$\frac{1}{5}$$

**(B)** 
$$\frac{1}{4}$$

(C) 
$$\frac{2}{5}$$

(B) 
$$\frac{1}{4}$$
 (C)  $\frac{2}{5}$  (D)  $\frac{9}{20}$  (E)  $\frac{1}{2}$ 

**(E)** 
$$\frac{1}{2}$$

point P, and there are 8 directions the lines could go, and there are 4 dots at

$$\frac{4\times 8}{80} = \boxed{(\mathbf{C})\frac{2}{5}}. \text{ $\sim$ heeeeeheeeeee}$$

#### **Problem 7**

Shauna takes five tests, each worth a maximum of 100 points. Her scores on the first three tests are 76,94, and 87. In order to average 81 for all five tests, what is the lowest score she could earn on one of the other two tests?

# **Solution 1**

We should notice that we can turn the information we are given into a linear equation and just solve for our set variables. I'll use the variables  $\mathcal X$  and  $\mathcal Y$  for the

$$\frac{76 + 94 + 87 + x + y}{5} = 81,$$

scores on the last two tests.

$$\frac{257+x+y}{5}=81.$$
 We can now cross multiply to get rid of the

denominator. 257+x+y=405, x+y=148. Now that we have this equation, we will assign y as the lowest score of the two other tests, and

so: x=100 , y=48 . Now we know that the lowest score on the two other tests is 48 . ~ aopsav

# **Solution 2**

Right now, she scored 76,94, and 87 points, with a total of 257 points. She wants her average to be 81 for her 5 tests so she needs to score 405 points in total. She needs to score a total of (405-257)148 points in her 2 tests. So the minimum score she can get is when one of her 2 scores is 100. So the least possible score she can get is (A) 48. ~heeeeeeheeeee

Note: You can verify that 48 is the right answer because it is the lowest answer out of the 5. Since it is possible to get 48, we are guaranteed that that is the right answer. ~~ gorefeebuddie

#### **Solution 3**

We can compare each of the scores with the average

of 81: 
$$76 \rightarrow -5$$
,  $94 \rightarrow +13$ ,  $87 \rightarrow +6$ ,  $100 \rightarrow 19$ ;

So the last one has to be -33 (since all the differences have to sum to 0), which corresponds to  $81-33=\boxed{48}$ 

## **Problem 8**

Gilda has a bag of marbles. She gives 20% of them to her friend Pedro. Then Gilda gives 10% of what is left to another friend, Ebony. Finally, Gilda gives 25% of what is now left in the bag to her brother Jimmy. What percentage of her original bag of marbles does Gilda have left for herself?

(A) 20 (B) 
$$33\frac{1}{3}$$
 (C) 38 (D) 45 (E) 54

#### **Solution 1**

After Gilda gives 20% of the marbles to Pedro, she has 80% of the marbles left. If she then gives 10% of what's left to Ebony, she has (0.8\*0.9) = 72% of what she had at the beginning. Finally, she gives 25% of what's left to her brother, so she has (0.75\*0.72) (E) 54. of what she had in the beginning left.~heeeeeeeheeeee

#### Solution 2

Suppose Gilda has 100 marbles.

Then she gives Pedro 20% of 100 = 20, she remains with 80 marbles.

Out of 80 marbles she gives 10% of 80 = 8 to Ebony.

Thus she remains with 72 marbles.

Then she gives 25% of 72 = 18 to Jimmy, finally leaving her with 54.

And 
$$\frac{54}{100}$$
=54%= **(E)** 54

~phoenixfire

# Solution 3 (Only if you have no time, do this method)

Since she gave away 20% and 10% of what is left and then another 25% of what is actually left, we can do 20+10+25 or 55%. But it is actually going to be a bit more than 55% because 10% of what is left is not 10% of the total amount. So

the only option that is greater than 100% - 55% is (E) 54. ~~ gorefeebuddie

# **Problem 9**

Alex and Felicia each have cats as pets. Alex buys cat food in cylindrical cans that are  $6\,\mathrm{cm}$  in diameter and  $12\,\mathrm{cm}$  high. Felicia buys cat food in cylindrical cans that are  $12\,\mathrm{cm}$  in diameter and  $6\,\mathrm{cm}$  high. What is the ratio of the volume one of Alex's cans to the volume one of Felicia's cans?

(A) 
$$1:4$$
 (B)  $1:2$  (C)  $1:1$  (D)  $2:1$  (E)  $4:1$ 

Using the formula for the volume of a cylinder, we get Alex,  $\pi 108$ , and Felicia,  $\pi 216$ . We can quickly notice that  $\pi$  cancels out on both sides, and that Alex's volume is 1/2 of Felicia's leaving  $1/2=\boxed{1:2}$  as the answer. ~aopsav

#### Solution 2

Using the formula for the volume of a cylinder, we get that the volume of Alex's can is  $3^2 \cdot 12 \cdot \pi$ , and that the volume of Felicia's can is  $6^2 \cdot 6 \cdot \pi$ . Now

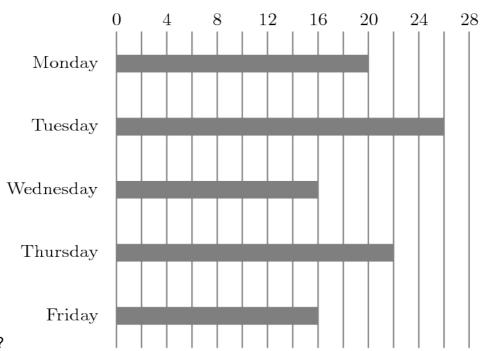

we divide the volume of Alex's can by the volume of Felicia's can, so we get  $\frac{1}{2}$ , which is  $(\mathbf{B})\ 1:2$  ~~SmileKat32

#### **Solution 3**

# **Problem 10**

The diagram shows the number of students at soccer practice each weekday during last week. After computing the mean and median values, Coach discovers that there were actually 21 participants on Wednesday. Which of the following

statements describes the change in the mean and median after the correction is Number of students at soccer practice

made?

- $(\mathbf{A})_{\!\mathsf{The}}$  mean increases by 1 and the median does not change.
- (B) The mean increases by 1 and the median increases by 1.
- (C) The mean increases by 1 and the median increases by 5.
- $(\mathbf{D})_{\mathsf{The mean increases}}$  by 5 and the median increases by 1.
- $(\mathbf{E})_{\text{The mean increases by } 5}$  and the median increases by 5.

#### **Solution 1**

On Monday, 20 people come. On Tuesday, 26 people come. On Wednesday, 16 people come. On Thursday, 22 people come. Finally, on Friday, 16 people come. 20+26+16+22+16=100, so the mean is 20. The median is (16,16,20,22,26)20. The coach figures out that actually 21 people come on Wednesday. The new mean is 21, while the new median is (16,20,21,22,26)21. The median and mean both

change, so the answer is (B) Another way to compute the change in mean is to notice that the sum increased by 5 with the correction. So the average  $_{\rm increased\ by}\,5/5=1$ 

#### **Problem 11**

The eighth grade class at Lincoln Middle School has  $93\,\mathrm{students}$ . Each student takes a math class or a foreign language class or both. There are 70 eighth graders taking a math class, and there are 54 eight graders taking a foreign language class. How many eighth graders take only a math class and not a foreign language class?

(A) 16 (B) 23 (C) 31 (D) 39 (E) 70

#### Solution 1

Let  $\mathcal{X}$  be the number of students taking both a math and a foreign language class.

By P-I-E, we get 70 + 54 - x = 93.

Solving gives us x=31.

But we want the number of students taking only a math class.

Which is 
$$70 - 31 = 39$$
.

~phoenixfire

#### Solution 2

We have 70+54=124 people taking classes. However we over-counted

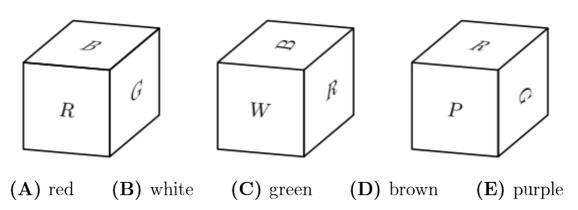

the number of people who take both classes. If we subtract the original amount of people who take classes we get that 31 people took the two classes. To find the amount of people who took only math class web subtract the people who didn't

take only one math class, so we get  $70-31=\boxed{\mathbf{D}\,39}$  -fath2012

We're basically just finding the number of students not taking a foreign language since all the rest would be taking only math.  $93-54=\boxed{\bf (D)\ 39}$ 

#### Problem12

The faces of a cube are painted in six different colors: red (R), white (W), green (G), brown (B), aqua (A), and purple (P). Three views of the cube are shown below. What is the color of the face opposite the aqua face?

## **Solution 1**

B is on the top, and R is on the side, and G is on the right side. That means that (image 2) W is on the left side. From the third image, you know that P must be on the bottom since G is sideways. That leaves us with the back, so the back must be A. The front is opposite of the back, so the answer is A.

# **Solution 2**

Looking closely we can see that all faces are connected with R except for A.

Thus the answer is (A) R

### **Problem 13**

A palindrome is a number that has the same value when read from left to right or from right to left. (For example 12321 is a palindrome.) Let N be the least three-digit integer which is not a palindrome but which is the sum of three distinct two-digit palindromes. What is the sum of the digits of N?

(A) 2 (B) 3 (C) 4 (D) 5 (E) 6

#### **Solution**

Note that the only positive 2-digit palindromes are multiples of 11,

namely  $11, 22, \dots, 99$ . Since N is the sum of 2-digit palindromes, N is necessarily a multiple of 11. The smallest 3-digit multiple of 11 which is not a palindrome is 110, so N=110 is a candidate solution. We must check that 110 can be written as the sum of three distinct 2-digit palindromes; this suffices

as 
$$110=77+22+11$$
. Then  $N=110$ , and the sum of the digits of  $N$  is  $1+1+0=$ 

#### **Problem 14**

Isabella has 6 coupons that can be redeemed for free ice cream cones at Pete's Sweet Treats. In order to make the coupons last, she decides that she will redeem one every  $10\,\mathrm{days}$  until she has used them all. She knows that Pete's is closed on Sundays, but as she circles the  $6\,\mathrm{dates}$  on her calendar, she realizes that no circled date falls on a Sunday. On what day of the week does Isabella redeem her first coupon?

- (A) Monday
- (B) Tuesday
- (C) Wednesday (D) Thursday
- (E) Friday

#### **Solution 1**

Let  $Day\ 1_{ ext{ to}}\ Day\ 2_{ ext{ denote}}$  a day where one coupon is redeemed and the day when the second coupon is redeemed.

If she starts on a Monday she redeems her next coupon on Thursday.

Thursday to Sunday

Thus (A) Monday is incorrect.

If she starts on a Tuesday she redeems her next coupon on Friday.

Friday to Monday.

Monday to Thursday

Thursday to Sunday.

Thus (B) Tuesday is incorrect.

If she starts on a Wednesday she redeems her next coupon on Saturday.

Saturday to Tuesday.

Tuesday to Friday.

Friday to Monday.

Monday to Thursday.

And on Thursday she redeems her last coupon.

No sunday occured thus (C) Wednesday is correct.

Checking for the other options,

If she starts on a Thursday she redeems her next coupon on Sunday.

Thus (D) Thursday is incorrect.

If she starts on a Friday she redeems her next coupon on Monday.

Monday to Thursday.

Thursday to Sunday.

Checking for the other options gave us negative results, thus the answer

~phoenixfire

# **Solution 2**

Let

$$Sunday \equiv 0 \pmod{7}$$

$$Monday \equiv 1 \pmod{7}$$

$$Tuesday \equiv 2 \pmod{7}$$

$$Wednesday \equiv 3 \pmod{7}$$

$$Thursday \equiv 4 \pmod{7}$$

$$Friday \equiv 5 \pmod{7}$$

$$Saturday \equiv 6 \pmod{7}$$

$$10 \equiv 3 \pmod{7}$$

$$20 \equiv 6 \pmod{7}$$

$$30 \equiv 2 \pmod{7}$$

$$40 \equiv 5 \pmod{7}$$

$$50 \equiv 1 \pmod{7}$$

$$60 \equiv 4 \pmod{7}$$

Which clearly indicates if you start form a  $x\equiv 3\pmod 7$  you will not get a  $y\equiv 0\pmod 7$ 

Any other starting value may lead to a  $y \equiv 0 \pmod{7}$ 

Which means our answer is  $( \mathbf{C} ) \ Wednesday$  ~phoenixfire

#### Solution 3

Like Solution 2, let the days of the week be numbers  $\pmod{7}$ . 3 and 7 are coprime, so continuously adding 3 to a number  $\pmod{7}$  will cycle through all numbers from 0 to 6. If a string of 6 numbers in this cycle does not contain 0, then if you minus 3 from the first number of this cycle, it will always be 0. So, the answer is  $\binom{\mathbf{C}}{Wednesday}$ . ~~SmileKat32

## **Solution 4**

Since Sunday is the only day that has not been counted yet. We can just add the 3 days as it will become  $(\mathbf{C}) \ Wednesday$ . ~~ gorefeebuddie Note: This only works when 7 and 3 are relatively prime.

#### **Problem 15**

On a beach 50 people are wearing sunglasses and 35 people are wearing caps. Some people are wearing both sunglasses and caps. If one of the people wearing a cap is selected at random, the probability that this person is is also

wearing sunglasses is  $\overline{5}$ . If instead, someone wearing sunglasses is selected at random, what is the probability that this person is also wearing a cap?

(A) 
$$\frac{14}{85}$$
 (B)  $\frac{7}{25}$  (C)  $\frac{2}{5}$  (D)  $\frac{4}{7}$  (E)  $\frac{7}{10}$ 

## **Solution 1**

$$\frac{2}{5}\cdot 35=14$$
 The number of people wearing caps and sunglasses is  $\frac{2}{5}\cdot 35=14$  . So then 14 people out of the 50 people wearing sunglasses also have

$$\frac{14}{50} = \boxed{(\mathbf{B})\frac{7}{25}}_{\text{heeeeeheeeee}}$$

#### **Problem 16**

Qiang drives 15 miles at an average speed of 30 miles per hour. How many additional miles will he have to drive at 55 miles per hour to average 50 miles per hour for the entire trip?

# **Solution 1(answer options)**

The only option that is easily divisible by 55 is 110. Which gives 2 hours of

travel. And by the formula 
$$\frac{15}{30} + \frac{110}{50} = \frac{5}{2}$$

$$And Average Speed = \frac{Total Distance}{Total Time}$$

$$_{\mathrm{Thus}}\frac{125}{50}=\frac{5}{2}$$

Both are equal and thus our answer is  $(\mathbf{D}) \ 110$  ~phoenixfire

## **Solution 2**

Note that the average speed is simply the total distance over the total time. Let the number of additional miles he has to drive be  $\mathcal{X}$ . Therefore, the total distance

is 
$$15+x$$
 and the total time (in hours) is  $\frac{15}{30}+\frac{x}{55}=\frac{1}{2}+\frac{x}{55}$  . We can

$$\frac{15+x}{\frac{1}{2}+\frac{x}{55}}=50.$$
 set up the following equation:

Simplifying the equation, we

get 
$$15 + x = 25 + \frac{10x}{11}.$$
 Solving the equation yields  $x = 110,$  so our

~twinemma

#### **Solution 3**

If he travels 15 miles at a speed of 30 miles per hour, he travels for 30 min. Average rate is total distance over total time

 $_{\rm so}\,(15+d)/(0.5+t)=50$  , where d is the distance left to travel and t

is the time to travel that distance. solve for d to get d=10+50t. you also know that he has to travel 55 miles per hour for some time, so d=55t plug that in for d to get 55t=10+50t and t=2 and

since 
$$d=55t, d=2\cdot 55=110$$
 the answer is (D)  $110$ 

## **Problem 17**

What is the value of the product

$$\left(\frac{1\cdot 3}{2\cdot 2}\right)\left(\frac{2\cdot 4}{3\cdot 3}\right)\left(\frac{3\cdot 5}{4\cdot 4}\right)\cdots\left(\frac{97\cdot 99}{98\cdot 98}\right)\left(\frac{98\cdot 100}{99\cdot 99}\right)?$$

(A) 
$$\frac{1}{2}$$
 (B)  $\frac{50}{99}$  (C)  $\frac{9800}{9801}$  (D)  $\frac{100}{99}$  (E)  $50$ 

#### **Solution 1**

$$\frac{1}{2} \cdot \left(\frac{3 \cdot 2}{2 \cdot 3}\right) \left(\frac{4 \cdot 3}{3 \cdot 4}\right) \cdots \left(\frac{99 \cdot 98}{98 \cdot 99}\right) \cdot \frac{100}{99}$$

The middle terms cancel, leaving us with

$$\left(\frac{1\cdot 100}{2\cdot 99}\right) = \boxed{\mathbf{(B)}\frac{50}{99}}$$

~phoenixfire

#### Solution 2

If you calculate the first few values of the equation, all of the values tend to  $\overline{2}$ ,

but are not equal to it. The answer closest to  $\overline{2}$  but not equal to it

$$(\mathbf{B})\frac{50}{99}$$

#### Solution 3

Rewriting the numerator and the denominator, we get  $\frac{2}{\left(99!\right)^2}$  . We can simplify

 $\underline{100 \cdot 98!}$ 

1

by canceling 99! on both sides, leaving us with:  $2 \cdot 99!$  We

rewrite 99! as  $99\cdot 98!$  and cancel 98!, which gets  $\boxed{\frac{30}{99}}$  . Answer B

## **Problem 18**

The faces of each of two fair dice are numbered 1, 2, 3, 5, 7, and 8. When the two dice are tossed, what is the probability that their sum will be an even number?

(A) 
$$\frac{4}{9}$$
 (B)  $\frac{1}{2}$  (C)  $\frac{5}{9}$  (D)  $\frac{3}{5}$  (E)  $\frac{2}{3}$ 

The approach to this problem: There are two cases in which the sum can be an even number: both numbers are even and both numbers are odd. This results in only one case where the sum of the numbers are odd (one odd and one even in any order) . We can solve for how many ways the 2 numbers add up to an odd number and subtract the answer from 1.

How to solve the problem: The probability of getting an odd number first

$$\frac{4}{6}=\frac{2}{3}.$$
 In order to make the sum odd, we must select an even number next.

The probability of getting an even number is  $\frac{2}{6}=\frac{1}{3}.$  Now we multiply the two

 $\frac{2}{3}\times\frac{1}{3}=2/9$  fractions:  $\frac{2}{3}$  however, this is not the answer because we could pick an even number first then an odd number. The equation is the same except backward and by the Communitive Property of Multiplication, the equations are it

 $\frac{2}{9}\times 2=\frac{4}{9}.$  does not matter is the equation is backward or not. Thus we do  $\frac{2}{9}$ 

$$1 - \frac{4}{9} = \boxed{(\mathbf{C})\frac{5}{9}}$$

getting an even number we do

- ViratKohli2018 (VK18)

#### **Solution 2**

We have a 2 die with 2 evens and 4 odds on both dies. For the sum to be even, the rolls must consist of 2 odds or 2 evens.

Ways to roll 2 odds (Case 4): The total number of ways to roll 2 odds is 4\*4=16, as there are 4 choices for the first odd on the first roll and 4 choices for the second odd on the second roll.

Ways to roll 2 evens (Case 2): Similarly, we have  $2\ast 2=4$  ways to roll 2 evens.

Totally, we have 6\*6=36 ways to roll 2 dies.

Therefore the answer is 
$$\frac{16+4}{36}=\frac{20}{36}=\frac{5}{9}$$
, or  $\boxed{\mathrm{C}}$ 

~A1337h4x0r

# **Solution 3 (Complementary Counting)**

We count the ways to get an odd. If the sum is odd, then we must have an even

and an odd. The probability of an even is  $\frac{-}{3}$ , and the probability of an odd is  $\frac{-}{3}$ . We have to multiply by 2! because the even and odd can be in any order. This

$$\frac{4}{9}$$
 gets us  $\frac{4}{9}$  , so the answer is  $1-\frac{4}{9}=\frac{5}{9}=\boxed{(\mathbf{C})}$  . - juliankuang

## **Solution 4**

To get an even, you must get either 2 odds or 2 evens. The probability of getting

 $\frac{4}{6}*\frac{4}{6}$  . The probability of getting 2 evens is  $\frac{2}{6}*\frac{2}{6}$  . If you add them

together, you get 
$$\frac{16}{36} + \frac{4}{36} = \boxed{(\mathbf{C})\frac{5}{9}}$$

#### Problem 19

In a tournament there are six teams that play each other twice. A team earns 3 points for a win. 1 point for a draw, and 0 points for a loss. After all the games have been played it turns out that the top three teams earned the same number of total points. What is the greatest possible number of total points for each of the top three teams?

## **Solution 1**

After fully understanding the problem, we immediately know that the three top teams, say team A, team B, and team C, must beat the other three teams D, E, F. Therefore, A, B, C must each

 $_{\mathrm{obtain}}\left(3+3+3\right)=9$  points. However, they play against each team twice, for a total of  $18\,\mathrm{points}$  against D, E, and F. For games between A, B, C, we have 2 cases. In both cases, there is an equality of points between A, B, and C.

Case 1: A team ties the two other teams. For a tie, we have 1 point, so we have (1+1)\*2=4 points (they play twice). Therefore, this case brings a total of 4+18=22 points.

Case 2: A team beats one team while losing to another. This gives equality, as each team wins once and loses once as well. For a win, we have 3 points, so a team gets  $3\times 2=6$  points if they each win a game and lose a game. This case brings a total of 18+6=24 points.

Therefore, we use Case 2 since it brings the greater amount of points, or  $\fbox{24}$  , so the answer is  $\fbox{C}$  . ~A1337h4x0r

Note that case 2 can be easily seen to be better as follows. Let  $x_A$  be the number of points A gets,  $x_B$  be the number of points B gets, and  $x_C$  be the number of points C gets. Since  $x_A = x_B = x_C$ , to maximize  $x_A$ , we can just maximize  $x_A + x_B + x_C$ . But in each match, if one team wins then the total sum increases by  $x_A + x_B + x_C$  points, whereas if they tie, the total sum increases by  $x_A + x_B + x_C$  points. So it is best if there are the fewest ties possible.

## **Solution 2**

$$(1st match(3) + 2nd match(1)) * number of teams(6) = 24, \boxed{C}$$

Explanation: So after reading the problem we see that there are 6 teams and each team versus each other twice. This means one of the two matches has to be a win, so 3 points so far. Now if we say that the team won again and make it 6 points, that would mean that team would be dominating the leader-board and the problem says that all the top 3 people have the same score. So that means the maximum amount of points we could get is 1 so that each team gets the same amount of matches won & drawn so that adds up to 4. 4 \* the number of teams(6)

= 24 so the answer is 
$$C$$

## **Problem 20**

How many different real numbers  $\boldsymbol{x}$  satisfy the equation  $(x^2-5)^2=16$ ?

**(A)** 0

**(B)** 1 **(C)** 2

**(D)** 4

**(E)** 8

# **Solution**

We have that  $(x^2 - 5)^2 = 16$  if and only if  $x^2 - 5 = \pm 4$ .

If  $x^2 - 5 = 4$ , then  $x^2 = 9 \implies x = \pm 3$ , giving 2 solutions.

If  $x^2 - 5 = -4$ , then  $x^2 = 1 \implies x = \pm 1$ , giving 2 more

**(D)**4 solutions. All four of these solutions work, so the answer is the equation is a quartic in  $\mathcal{X}$ , so by the Fundamental Theorem of Algebra, there can be at most four real solutions.

#### **Problem 21**

What is the area of the triangle formed by the lines y=5 , y=1+x

and  $y = 1 - x_{?}$ 

(A) 4 (B) 8 (C) 10 (D) 12

**(E)** 16

# **Solution 1**

You need to first find the coordinates where the graphs intersect. y=5

and y = x + 1 intersect at (4,5), y = 5, and y = 1 - x intersect

 $_{\mathrm{at}}\left(-4,5\right)y=1-x$  and y=1+x intersect at (0,1) . Using

 $\left(\frac{(20-4)-(-20+4)}{2}\right)\frac{32}{2}$ the Shoelace Theorem you get

~heeeeeeheeeee

Graphing the lines, we can see that the height of the triangle is 4, and the base is

$$4 \cdot 8$$

8. Using the formula for the area of a triangle, we get 2 which is equal

#### Problem 22

A store increased the original price of a shirt by a certain percent and then lowered the new price by the same amount. Given that the resulting price

was 84% of the original price, by what percent was the price increased and decreased?

# **Solution 1**

Suppose the fraction of discount is  $\mathcal{X}$ . That

$$_{\rm means}\,(1-x)(1+x)=0.84, \, {\rm so}\,1-x^2=0.84,$$

and  $(x^2)=0.16$ , obtaining x=0.4. Therefore, the price was increased and decreased by 40%, or  $\boxed{(\mathbf{E})\ 40}$ 

# **Solution 2(Answer options)**

**(E)** 40 Let the price be 100 and then trying for each option leads to -phoenixfire

## **Solution 3**

Let x be the discount. We can also work in reverse such as (84) $\left(\frac{100}{100+x}\right)_{=100.}$ 

Thus 8400 = (100 + x)(100 - x). Solving for x gives us x=40, -40. But x has to be positive. Thus x= 40.

#### **Problem 23**

After Euclid High School's last basketball game, it was determined that 4 of the

team's points were scored by Alexa and  $\overline{7}$  were scored by Brittany. Chelsea scored  $15\,\mathrm{points}$  . None of the other  $7\,\mathrm{team}$  members scored more than  $2\,\mathrm{points}$ What was the total number of points scored by the other 7 team members?

(A) 10

**(B)** 11 **(C)** 12 **(D)** 13

**(E)** 14

1

#### **Solution 1**

 $\frac{total\ points}{4} \quad \frac{2(total\ points)}{7} \text{ are integers, we}$ 

have  $28|{
m total\ points}|$  . We see that the number of points scored by the other team members is less than or equal to 14 and greater than or equal to 0. We let the total number of points be t and the total number of points scored by the other team members, which means that

$$\frac{t}{4} + \frac{2t}{7} + 15 + x = t \implies 0 \le \frac{13t}{28} - 15 = x \le 14$$

, which means  $15 \leq \frac{13t}{28} \leq \underbrace{29}_{\text{. The only value of } t \text{ that satisfies all }}$ 

conditions listed is 56, so  $x = \boxed{ (\mathbf{B})11}$  . - juliankuang (lol im smart.)

 $\frac{t}{4}+\frac{2t}{7}+15+x=t \\ \text{where } t \text{ is the total number of points scored and } x \leq 14 \\ \text{is the number of points scored by the remaining 7 team members, we can simplify to obtain the Diophantine}$ 

equation 
$$x+15=\frac{13}{28}t$$
, or  $28x+28\cdot 15=13t$ . Since  $t$  is necessarily divisible by 28, let  $t=28u$  where  $u\geq 0$  and divide by 28 to obtain  $x+15=13u$ . Then it is easy to see  $u=2$  ( $t=56$ ) is the only candidate, giving  $x=\boxed{(\mathbf{B})11}$ . -scrabbler94

## **Solution 3**

Fakesolve: We first start by setting the total number of points as 28,

since  ${
m lcm}(4,7)=28$ . However, we see that this does not work since we surpass the number of points just with the information given

$$28\cdot\frac{1}{4}+28\cdot\frac{2}{7}+15>28$$
 ). Next, we assume that the total number of points scored is  $56$ . With this, we have that Alexa, Brittany, and Chelsea

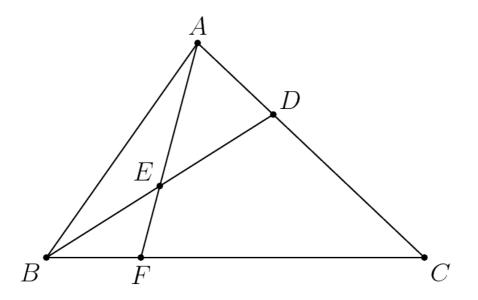

score: 
$$56 \cdot \frac{1}{4} + 56 \cdot \frac{2}{7} + 15 = 45$$
 , and thus, the other seven players

would have scored a total of  $56-45=\ensuremath{\boxed{(\mathbf{B})11}}$  (We see that this works since we could have 4 of them score 2 points, and the other 3 of them score 1 point) -aops5234

# **Problem 24**

In triangle ABC, point D divides side  $\overline{AC}$  so

that AD:DC=1:2. Let E be the midpoint of  $\overline{BD}$  and let F be the point of intersection of line BC and line AE. Given that the area of  $\triangle ABC$  is 360, what is the area of  $\triangle EBF$ ?

#### **Solution 1**

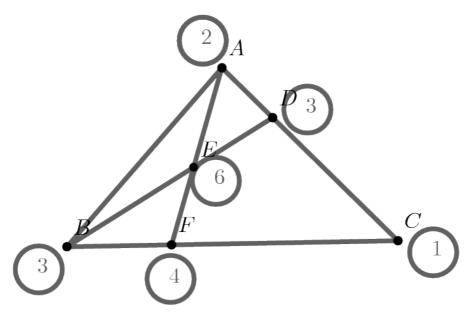

Draw X on  $\overline{AF}$  such that XD is parallel to BC. That makes triangles BEF and EXD congruent since BE=ED. FC=3XD so BC=4BF.

Since 
$$AF=3EF$$
 (  $XE=EF$  and  $AX=\frac{1}{3}AF$  ,

 $XE=EF=\frac{1}{3}AF$  ), the altitude of triangle BEF is equal to  $\frac{1}{3}$  of the altitude of ABC . The area of ABC is 360, so the area

$$BEF = \frac{1}{3} \cdot \frac{1}{4} \cdot 360 = \boxed{\textbf{(B)} \ 30}_{\text{~heeeeeeheeeee}}$$

# **Solution 2 (Mass Points)**

First, when we see the problem, we see ratios, and we see that this triangle basically has no special properties (right, has medians, etc.) and this screams mass points at us.

First, we assign a mass of 2 to point A. We figure out that C has a mass of 1 since  $2\times 1=1\times 2$ . Then, by adding 1+2=3, we get that point D has a mass of 3. By equality, point B has a mass of 3 also.

Now, we add 3+3=6 for point E and 3+1=4 for point F.

Now, BF is a common base for triangles ABF and EBF, so we figure out that the ratios of the areas is the ratios of the heights which

$$\frac{AE}{EF}=2:1$$
 . So,  $EBF$  's area is one third the area of  $ABF$  , and we  $1$ 

know the area of ABF is  $\overline{4}$  the area of ABC since they have the same heights but different bases.

So we get the area of 
$$EBF$$
 as  $\frac{1}{3} \times \frac{1}{4} \times 360 =$  [(B)  $30$ ]-Brudder

Note: We can also find the ratios of the areas using the reciprocal of the product of the mass points of EBF over the product of the mass points

of 
$$ABC$$
 which is  $\frac{2\times3\times1}{3\times6\times4}\times360$  which also yields (B)  $30$  Brudder

## **Solution 3**

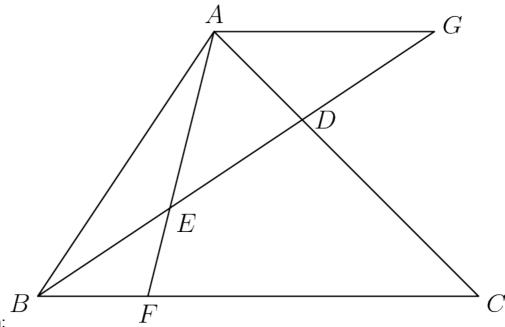

triangles AED and CED, which is respectively 60 and 120. So,  $\overline{FC}$  is 60-1

BF

equal to  $\overline{180}$  =  $\overline{3}$ , so the area of triangle ABF is 90. That minus the area of triangle ABE is  $(\mathbf{B})$  30. ~~SmileKat32

# **Solution 4 (Similar Triangles)**

Extend  $\overline{BD}$  to G such that  $\overline{AG} \parallel \overline{BC}$  as

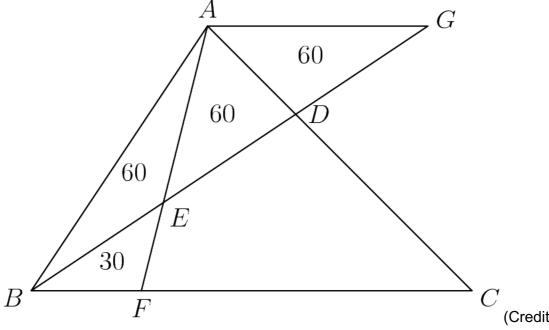

shown:

Then  $\triangle ADG \sim \triangle CDB$  and  $\triangle AEG \sim \triangle FEB$ . Since CD=2AD, triangle CDB has four times the area of triangle ADG. Since [CDB]=240, we get [ADG]=60.

Since  $[AED]_{\mbox{is also}}\,60$ , we have ED=DG because

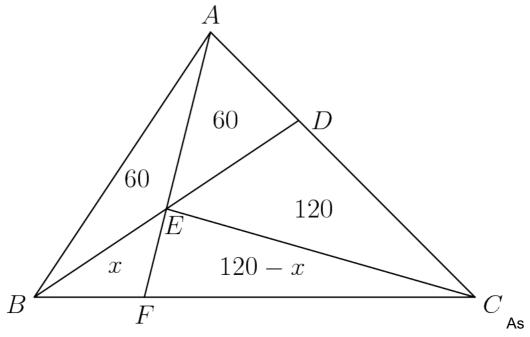

triangles AED and ADG have the same height and same areas and so their bases must be the congruent. Thus triangle AEG has twice the side lengths and therefore four times the area of triangle BEF,

giving 
$$[BEF] = (60 + 60)/4 = \boxed{\textbf{(B)} \ 30}$$

#### to MP8148 for the idea)

# **Solution 5 (Area Ratios)**

before we figure out the areas labeled in the diagram. Then we note

$$\frac{EF}{AE} = \frac{x}{60} = \frac{120-x}{180}.$$
 Solving gives  $x = \boxed{\textbf{(B)} \ 30}$ . (Credit to scrabbler94 for the idea)

# **Solution 6 (Coordinate Bashing)**

Let ADB be a right triangle, and BD=CD

$$_{\mathrm{Let}}\,A=(-2\sqrt{30},0)$$

$$B = (0, 4\sqrt{30})$$

$$C = (4\sqrt{30}, 0)$$

$$D = (0, 0)$$

$$E = (0, 2\sqrt{30})$$

$$F = (\sqrt{30}, 3\sqrt{30})$$

The line  $\overrightarrow{AE}$  can be described with the equation  $y=x-2\sqrt{30}$ 

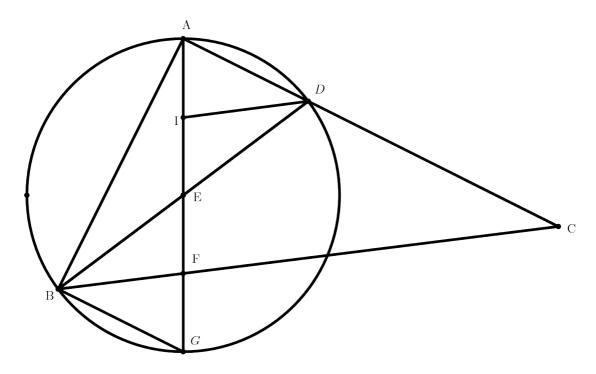

The line 
$$\overrightarrow{BC}$$
 can be described with  $x+y=4\sqrt{30}$ 

Solving, we get 
$$x=3\sqrt{30}$$
 and  $y=\sqrt{30}$ 

Now we can find  $EF=BF=2\sqrt{15}$ 

$$[\triangle EBF] = \frac{(2\sqrt{15})^2}{2} = \boxed{\textbf{(B) } 30} \blacksquare$$

-Trex4days

Let  $A[\Delta XYZ]_{=Area}$  of Triangle XYZ

$$A[\Delta ABD] : A[\Delta DBC] :: 1 : 2 :: 120 : 240$$

 $A[\Delta ABE] = A[\Delta AED] = 60$  (the median divides the area of the triangle into two equal parts)

Construction: Draw a circumcircle around  $\Delta ABD$  with BD as is diameter. Extend AF to G such that it meets the circle at G . Draw line BG

$$A[\Delta ABD] = A[\Delta ABG] = 120_{\, (\rm Since} \, \Box ABGD \, {\rm is \, cyclic})$$

But  $A[\Delta ABE]_{\rm is\ common\ in\ both\ with\ an\ area\ of\ 60.}$ 

$$SO, A[\Delta AED] = A[\Delta BEG]$$

\therefore  $A[\Delta AED]\cong A[\Delta BEG]_{\mbox{(SAS Congruency Theorem)}}.$  In  $\Delta AED$ , let DI be the median of  $\Delta AED$ .

Which means 
$$A[\Delta AID] = 30 = A[\Delta EID]$$

Rotate  $\Delta DEA$  to meet D at B and A at G. DE will fit exactly in BE (both are radii of the circle). From the above solutions,  $\frac{AE}{EF}=2:1$ 

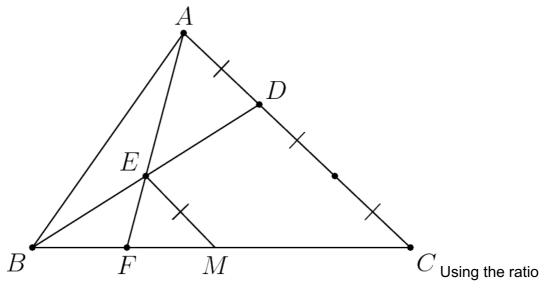

AE is a radius and EF is half of it implies EF =  $\cfrac{radius}{2}$  .

Which means  $A[\Delta BEF]\cong A[\Delta DEI]$ 

$$_{\rm Thus}\,A[\Delta BEF] = \boxed{ ({\bf B}) \ 30 }$$

~phoenixfire & flamewavelight

## **Solution 8**

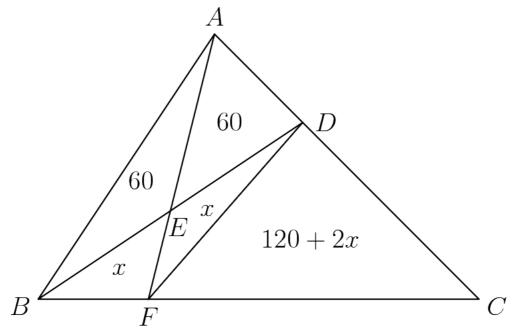

of  $\overline{AD}$  and  $\overline{CD}$ , we find the area of  $\triangle ADB$  is 120 and the area of  $\triangle BDC$  is 240. Also using the fact that E is the midpoint of  $\overline{BD}$ , we know  $\triangle ADE = \triangle ABE = 60$ . Let M be a point such  $\overline{EM}$  is parellel to  $\overline{CD}$ . We immediatley know that  $\triangle BEM \sim BDC$  by 2. Using that we can conclude EM has ratio 1.

Using  $\triangle EFM \sim \triangle AFC$  , we get EF:AE=1:2 . Therefore using the fact that  $\triangle EBF$  is in  $\triangle ABF$  , the area has

ratio  $\triangle BEF: \triangle ABE = 1:2$  and we know  $\triangle ABE$  has

## **Solution 9**

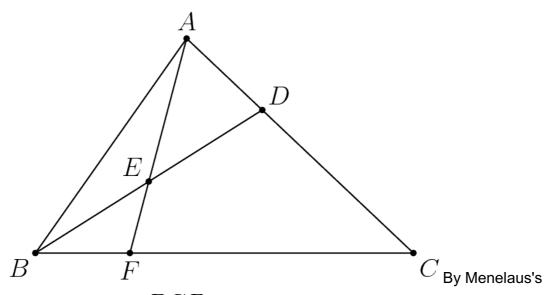

Labeling the areas in the diagram, we have:

$$[DBC] = 240 = [BFE] + [FED] + [FDC] = x + x + 120 + 2x = 120 + 4x$$
  
so  $240 = 120 + 4x, 120 = 4x, 30 = x$ .

So our answer is (B) 30. ~~RWhite

# **Solution 10 (Menelaus's Theorem)**

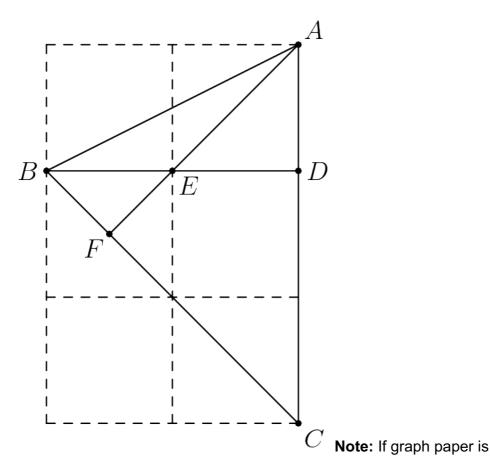

Theorem on triangle BCD, we have

$$\frac{BF}{FC} \cdot \frac{CA}{DA} \cdot \frac{DE}{BE} = 3\frac{BF}{FC} = 1 \implies \frac{BF}{FC} = \frac{1}{3} \implies \frac{BF}{BC} = \frac{1}{4}.$$

Therefore,

$$[EBF] = \frac{BE}{BD} \cdot \frac{BF}{BC} \cdot [BCD] = \frac{1}{2} \cdot \frac{1}{4} \cdot \left(\frac{2}{3} \cdot [ABC]\right) = \boxed{\textbf{(B) } 30}.$$

# **Solution 11 (Graph Paper)**

unavailable, this solution can still be used by constructing a small grid on a sheet of blank paper.

As triangle ABC is loosely defined, we can arrange its points such that the diagram fits nicely on a coordinate plane. By doing so, we can construct it on graph paper and be able to visually determine the relative sizes of the triangles.

As point D splits line segment  $\overline{AC}$  in a 1:2 ratio, we draw  $\overline{AC}$  as a vertical line segment 3 units long. Point D is thus 1 unit below point A and 2 units above point C. By definition, Point E splits line segment  $\overline{BD}$  in a 1:1 ratio, so we draw  $\overline{BD}$  2 units long directly left of D and draw E directly between B and D, 1 unit away from both.

We then draw line segments  $\overline{AB}$  and  $\overline{BC}$ . We can easily tell that triangle ABC occupies 3 square units of space. Constructing line AE and drawing F at the intersection of AE and BC, we can easily see that

triangle EBF forms a right triangle occupying  $\overline{\overset{-}{4}}$  of a square unit of space.

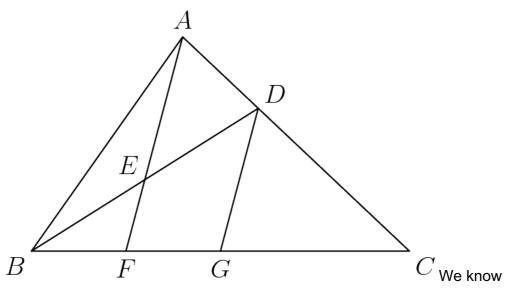

The ratio of the areas of triangle EBF and triangle ABC is

$$\frac{1}{4} \div 3 = \frac{1}{12}$$
 , and since the area of triangle  $ABC$  is  $360$  , this

means that the area of triangle EBF is  $\frac{1}{12}\times 360=$  [(B)  $\,30$  ]. ~emerald\_block

**Additional note:** There are many subtle variations of this triangle; this method is one of the more compact ones. ~i\_equal\_tan\_90

## **Solution 12**

$$AD=\frac{1}{3}AC$$
 , so  $[ABD]=\frac{1}{3}[ABC]=120$  . Using the

same method, since 
$$BE=rac{1}{2}BD$$
 ,  $[ABE]=rac{1}{2}[ABD]=60$  .

Next, we draw G on  $\overline{BC}$  such that  $\overline{DG}$  is parallel to  $\overline{AF}$  and create segment DG. We then observe that  $\triangle AFC \sim \triangle DGC$ , and since AD:DC=1:2,FG:GC is also equal to 1:2. Similarly (no pun intended),  $\triangle DBG \sim \triangle EBF$ , and since BE:ED=1:1,BF:FG is also equal to 1:1. Combining the information in these two ratios, we find

that 
$$BF:FG:GC=1:1:2$$
, or equivalently,  $BF=\frac{1}{4}BC$ 

Thus, 
$$[BFA] = \frac{1}{4}[BCA] = 90$$
 . We already know 
$$_{\rm that}[ABE] = 60, {\rm so~the~area}$$
 of  $\triangle EBF$  is 
$$[BFA] - [ABE] = \boxed{ {\bf (B)} \ 30}$$
 . ~i\_equal\_tan\_90

# Solution 13(fastest solution if you have no time)

The picture is misleading. Assume that the triangle ABC is right. Then find two factors of 720 that are the closest together so that the picture becomes easier in your mind. Quickly searching for squares near 720 to use difference of squares, we find 24 and 30 as our numbers. Then the coordinates of D are 10,16(note, A=0,0). E is then 5,8. Then the equation of the line AE is -16x/5+24=y. Plugging in y=0, we have x=15/2.Now notice that we have both the height and the base of EBF. Solving for the area, we have (8)(15/2)(1/2)=30.

#### **Problem 25**

Alice has 24 apples. In how many ways can she share them with Becky and Chris so that each of the three people has at least two apples?

#### **Solution 1**

We use stars and bars. The problem asks for the number of integer solutions (a,b,c) such that a+b+c=24 and  $a,b,c\geq 2$ . We can subtract 2 from a,b,c, so that we equivalently seek the number of non-negative integer solutions to a'+b'+c'=18. By stars and bars (using 18 stars and 2 bars), the number of solutions

## **Solution 2**

 $\frac{\text{Without loss of generality}}{\text{are } 19 \text{ ways to split the rest of the apples with Becky and Chris. If Alice}}$ 

has 3 apples, there are 18 ways to split the rest of the apples with Becky and Chris. If Alice has 4 apples, there are 17 ways to split the rest. So the total number of ways to split 24 apples between the three friends is equal

$$_{\text{to}} 19 + 18 + 17.... + 1 = 20 \times \frac{19}{2} = \boxed{\textbf{(C)} 190}$$

#### **Solution 3**

Let's assume that the three of them have  $\mathcal{X}, \mathcal{Y}, \mathcal{Z}$  apples. Since each of them has to have at least 2 apples, we say

that 
$$a + 2 = x, b + 2 = y$$
 and  $c + 2 = z$ .

Thus,  $a+b+c+6=24 \implies a+b+c=18$ , and so by stars and bars, the number of solutions for this is

$$\binom{n+k-1}{k} \implies \binom{18+3-1}{3-1} \implies \binom{20}{2} = \boxed{(\mathbf{C}) \ 190}$$
